(57)Abstract: To prevent transmission efficiency from being degraded due to a change of modulation schemes. A terminal apparatus (100) decides, in response to an operator's activation of an application, which line is to be given a priority, an upstream line or a downstream line, and requests a base station apparatus (200). The base station apparatus (200) detects, from signals received from the terminal apparatus with which it must communicate at a variable transmission rate, a request signal related to the upstream
